

The Toronto Raccoon Activity Index*

A Serious Exploration of a Joke Dataset

Lewis Sang

October 1, 2026

The raccoon (*Procyon lotor*) in Toronto is a well-liked, if controversial, animal population that presents risks for both human health and property. This project examines the Toronto Raccoon Activity Index, a false dataset generated for April Fool’s Day 2026, as a model for actual raccoon behaviour and reflects on how its design mirrors common understandings of raccoons. This paper argues that the design and results of the false dataset reveals tensions in how these ‘pests’ are viewed and sought to be managed within human-centric urban environments.

1 Introduction

The raccoon (*Procyon lotor*) is a mammal omnivore native to North America. While predominately located on the East coast and the Great Lakes regions, raccoon populations have spread rapidly across the continent since the introduction of European colonists and the fur trade (Rosatte (2000)). Notably, they have found considerable success in metropolitan areas, due to factors such as readily available food sources like waste bins and gardens, accessible habitats in housing and buildings, and a lack of natural predators (Werb (2026)). However, raccoons also pose risks to their neighbours, as they commonly carry diseases such as rabies and *Baylisascaris procyonis*, both of which cause severe neurological harm in humans (French et al. (2022)). Moreover, raccoons nesting often cause dangerous and costly property damage.

In Toronto, the raccoon is a divisive figure. The “raccoon problem” is one that has plagued Toronto City Council, with a number of mayors investing in methods of population control, “raccoon-proof” garbage bins, and even floating the possibility of extermination programs (CBC News (2014)). Conversely, Conrad - a dead raccoon left on a sidewalk for fourteen hours that became a national media sensation - was memorialised with a heritage plaque on the corner of Yonge and Church on the eve of his tenth anniversary (Baldin (2025)). The raccoon is seen as a symbol of adaptability, resilience, and part of life in the Greater Toronto Area (Renzetti (2015)) - so much so that City of Toronto’s Open Data team released a Toronto Raccoon Activity Index (TRAJ) dataset on April 1, 2026, describing the raccoon as a “prominent feature of Toronto’s urban environment” that necessitated detailed, hourly observations across the 25 wards of the city (City of Toronto (2026)). While the TRAJ is ostensibly a joke and likely randomly generated, its mere existence symbolises the complex relationship between the raccoons and the citizens of Toronto.

This paper seeks to analyse the TRAJ through two lenses - as a legitimate dataset of raccoon behaviour across the city, and as a deliberately created product that may reveal underlying assumptions and biased understandings of the city’s residents and their relationship to the environments in which they live.

2 Data

The two datasets utilised in this paper were obtained through the OpenDataToronto Library - the Toronto Raccoon Activity Index (City of Toronto (2026)), and the 2021 One Variable sheet from the Ward Profiles (25-Ward Model) dataset (City of Toronto (2024)). Data was extracted using R (R Core Team (2025)) and the `opendatatoronto` library (Gelfand (2025)), and cleaned using the `tidyverse` package (Wickham et al. (2019)).

2.1 The Toronto Raccoon Activity Index

2.1.1 Description

The TRAI details hourly raccoon appearances across the 25 wards of the GTA from January 1 to March 30 of 2024 (Table 1). Additionally, the TRAI records the number of compromised green compost bins, average raccoon weight in kilograms, and the raccoon’s “confidence.” Given that there is no given methodology or definition for characterising raccoon behaviour, this metric was not used in analysis.

Table 1: Sample Raccoon Activity Across 5 Wards of Toronto January 1, 2024 00:00

Ward	Units Observed	Bins Compromised	Raccoon Confidence	Average Weight (kg)
Davenport	20	13	10.0	6.06
Spadina-Fort York	16	10	10.0	4.85
University- Rosedale	19	14	10.0	6.21
Toronto-St. Paul’s	12	7	7.9	6.05
Toronto Centre	18	11	10.0	6.48
Toronto-Danforth	19	14	10.0	5.19

Alongside raccoon behaviour, the TRAI records human-raccoon interactions (Table 2). These interactions are defined as confrontations (described as “standoffs”) with the number of incidents, average duration of the interaction in seconds, proximity to a patio, and complaints filed are recorded.

Table 2: Raccoon-Human Interactions in Toronto-Danforth January 1, 2024 from 00:00 to 06:00

Hour	Human Raccoon Confrontations	Average Standoff Duration (s)	Patio Proximity	Complaints Logged
0	4	31	FALSE	2
1	1	25	FALSE	2
2	3	16	FALSE	1
3	2	26	FALSE	2
4	0	0	FALSE	0
5	0	0	FALSE	0

2.1.2 Cleaning and Aggregation

This data can be analysed across a number of categories, such as creating an average of raccoon observations per hour, or the daily average raccoon appearances in the quarter. The `aggregate` function of the base R `stats` package is used to create these averaged datasets (Table 3).

Table 3: Daily and Hourly Averages of Observed Raccoons Across Toronto from January to March 2024

(a) Daily Average		(b) Hourly Average	
Date	Raccoons Observed	Hour	Raccoons Observed
2024-01-01	5.72	0	15.05
2024-01-02	5.68	1	15.11
2024-01-03	5.77	2	15.04
2024-01-04	5.71	3	15.06
2024-01-05	5.72	4	2.60
2024-01-06	7.56	5	2.63

2.2 Ward Profiles

2.2.1 Description

Table 4: Types of Household Dwellings of Toronto and Sample Wards

Dwelling Structure	Toronto	Ward 1	Ward 2	Ward 3	Ward 4	Ward 5
Single-detached house	270350	11270	21860	18585	8855	13190
Semi-detached house	73160	1425	875	1365	4215	3315
Row house	63170	3645	2005	2340	1175	1265
Apartment or flat in a duplex	46470	3790	785	1500	2120	1845
Apartment in a building that has fewer than five storeys	162260	2015	1925	11100	14040	7105
Apartment in a building that has five or more storeys	542625	15980	17860	30645	18955	18300
Other single-attached house	2760	10	25	35	70	35
Movable dwelling	95	0	0	0	15	0

The Ward Profiles dataset is based on the 2021 Census of Population conducted by the Government of Canada. The dataset records the demographics for the population and households of

each ward, including ethnocultural origins, language, education status, and employment. See Table 4 for a sample of how the data is structured.

2.3 Cleaning

As the TRAI and the Ward Profiles share the same ID, each ward’s demographics can be compared with corresponding raccoon behaviour. The Ward Profiles dataset includes average and median values for income and average household size, which are then isolated and merged with existing raccoon behaviour datasets.

3 Results

3.1 City-Wide Behaviour

Figure 1: Average Raccoon Appearances Across Toronto

The TRAI featured a total of 54 000 observations over the timespan of the dataset. Overall, a total of 335 957 observations of raccoons were recorded. Raccoons observances peaked from the hours of 20:00 to 4:00 around three to four times a month (Figure 1). Moreover, a higher presence of raccoons and number of observations directly correlates with higher raccoon activity, including compromised bins (Figure 2) and interactions with humans. These interactions also directly correlate to logged complaints.

3.2 By Ward

Given the direct correlations between raccoon observations, raccoon activity, and human-raccoon interactions, graphing these occurrences across the 25 wards reveals similar patterns

(a) Raccoons Observed Compared to Number of Green Bins Compromised (b) Number of Compromised Green Bins to Human-Raccoon Incidents

(c) Number of Compromised Green Bins to Submitted Complaints (d) Human-Raccoon Incidents to Submitted Complaints

Figure 2: Correlations of Raccoon Impact (with Jitter)

and outliers (Figure 3). There are eight wards that are consistent outliers - Beaches-East York, Davenport, Etobicoke-Lakeshore, Parkside-High Park, Spadina-Fort York, Toronto-Danforth, Toronto Centre, and University-Rosedale. However, examining the neighbourhood demographics do not reflect similarly notable outliers in median income or average number of members in a household (Figure 4).

Figure 3: Raccoon Behaviour Across Wards

Figure 4: Ward Demographics

4 Discussion

General activity trends as seen in Figure 1 represent raccoons as nocturnal animals primarily motivated by the open presence of compost bins, as they appear to be active once a week, possibly corresponding to the weekly garbage schedule. The TRAI also suggests a direct

correlation to the number of raccoon appearances with destructive behaviours, such as opening bins and interacting with humans. The correlation between complaints logged and human interactions with raccoons also reflects a combative relationship.

There are number of factors that likely give away the false nature of this dataset, such as the date of publication and the contact email address being `aprilfools2026@toronto.ca` (City of Toronto (2026)). However, there are also a number of notable characteristics of the data when further analysed as trends and aggregations, as noted in the Results section above. These include extremely abrupt shifts in raccoon occurrences as seen in Figure 1a, similar positive correlations in Figure 2, and extremely similar trends and outliers across across in Figure 3.

If the TRAI was a legitimately collected dataset, these results may have reflected the behaviour of a raccoon population in a metropolitan area as it attempts to adapt. However, as a deliberately *created* dataset, these invented relationships reveal the “common-sense” assumptions that underlay the city’s understanding of raccoons - namely, that they are a destructive and antagonistic force that directly impacts the population’s quality of life. In news coverage and communications from the municipal government, managing the growing raccoon population is often phrased as a war, a problem, or a source of fear that must be mitigated (CBC News (2014), Renzetti (2015)). However, Rosatte (2000) argues that most intervention strategies have been unsuccessful in lowering raccoon populations across Ontario, despite additional factors such as widespread disease.

As part of its creation, the TRAI determined eight wards to be significant outliers, compared to the smaller variance between recorded observances in the other wards (Figure 3). However, these differences in raccoon behaviour do not correlate with demographic data or other factors that have been studied as influencing raccoon distribution, such as types of residential zoning (French et al. (2022)). As such, why these specific wards were selected as sites of higher raccoon activity is unclear. Additional factors that are not available through the Ward Profiles, such as the number of restaurants or businesses as sources of food waste in each ward, may have greater significance and offer greater insights into how neighborhood infrastructures and urban planning influence raccoon populations. This randomness also suggests a gap in knowledge on how humans and cities affect raccoon behaviour.

5 Conclusion

Under-recognised in the public conversation around Toronto raccoons is the fact that urban development has resulted in their displacement and is exacerbating their dangerous behaviours. The raccoon’s presence is less of an invasion and more of an enduring that existed long before the neighbourhood itself. As Pacini-Ketchabaw and Nxumalo (2016) argue, the raccoon and its flourishing in the urban environment unsettles the “perceived divide” of nature and civilization, where their “mischievous” and “trickster” ways demand urban residents, typically settler colonialists, to confront their entanglements with the ecosystem and the non-human actors around them.

Despite being designed as a joke, the Toronto Raccoon Activity Index demonstrates a number of underlying beliefs of the relationship between the residents of Toronto and the raccoon populations. Through the design of data generation, raccoons are framed as destructive to property and intrusive to residents' day-to-day lives, requiring some type of governmental intervention via filing complaints to the city. Conversations around managing raccoon populations focus on direct interventions such as animal control, such as capture and relocation (Rosatte et al. (1992)), or municipal legislation, such as changing waste management schedules (Powell (2014)), suggesting that raccoons are a type of pest or "trash" to be studied, acted upon, and ultimately managed or eliminated for human benefit. These implications are particularly interesting given that raccoons are one of the few species that have found significant success in the urban environment despite climate change and habitat destruction (Bateman and Fleming (2012)). Raccoons are noted for their intelligence and adaptability, allowing them to effectively co-exist in urban environments that continue to be hostile to their existence (Lazure and Weladji (2024)). These tensions are especially prevalent within the TRAI as a text that conveys both affection and distaste for this "native pest."

The limitations of this dataset are difficult to assess, as the intention and methodology behind the false data's generation are not available for study. Further investigations may include comparing the TRAI to actual studies of Toronto's raccoon populations, as well as other impacts of raccoons on neighbourhoods, such as cases of rabies and *Baylisascaris procyonis* over a similar time period. Examinations of public sentiment towards raccoons and the City of Toronto's management of the population may also provide further socio-cultural understandings of the raccoon within the city.
